## Supplemental Appendix

### 1 The Primary Care Policy (PCP) Model.

Here, we follow standard international modeling guidelines to describe the programming of the model;<sup>1</sup> code for replication and extension of our results are available concurrent with publication at: http://sdr.stanford.edu. The model was programmed in *R* (The R Foundation for Statistical Computing, Vienna).

The first stage of the model involves the construction of population tables in which table rows reflect individual patients and table columns refer to demographic features of each patient. Specifically, we generate a simulated patient population to reflect the demographic makeup of each state and Washington DC (Supplemental Appendix Table 1). Individuals in the model are assigned demographic features in a probabilistic manner to match US Census Bureau estimates<sup>2</sup> of the covariance between the following characteristics: age (in years), sex (dichotomous), race/ethnicity (in standard Census categories of non-Hispanic White, non-Hispanic Black, Hispanic, and Other), and income (expressed as a poverty income ratio to correct for household size). To assign simulated individuals these characteristics, we Monte Carlo sample from the joint probability distributions of these demographic features using the Census data for each state, constructing a demographically-representative state population. The joint probability distributions are captured using a copula function, which allows the covariance between variables to be taken into account.<sup>3</sup> The input data are freelyaccessible online (https://www.census.gov/cps/data/). Based on these demographic features and state of residence, individuals are similarly assigned an insurance status (private, Medicare, Medicaid/CHIP, or self-pay) based on their demographic characteristics and their state of residence, again using Monte Carlo sampling from each state's distribution of insurance among each demographic group.<sup>2</sup> The insurance data are also freely-accessible online (http://kff.org/state-category/health-coverage-uninsured/).

Insurance status assignments were updated to reflect current insurance coverage estimates following the Affordable Care Act.<sup>4</sup>

The second stage of the model assigns diagnoses to individuals by ICD-9 code based on data from the Agency for Healthcare Research and Quality (AHRQ),<sup>5</sup> which is linked to the number of outpatient medical visits and reimbursements associated with those visits given patient demographics, insurance, and diagnoses. As with the demographic assignment, we used Monte Carlo sampling to assign each simulated individual a diagnosis and number of practice visits per year by sampling from that individual's demographic and insurance group in the data, using survey sample weights to account for differential selection and non-response in the AHRQ data. The data for this stage are also freely-accessible online

(http://meps.ahrq.gov/mepsweb/data\_stats/download\_data\_files.jsp) and the statistical code for migrating the data from the baseline SAS format to *R* format and assembling the data using appropriate sample weights are also freely-accessible online (https://github.com/ajdamico/usgsd/tree/master/Medical%20Expenditure%20Panel%20S urvey). Using this data and code, we were able to estimate utilization and reimbursements per visit across simulated patients. The visits were distributed among physicians to match data from the Medical Group Management Association (MGMA) database on rates of encounters among primary care practitioners per year<sup>6</sup> to express revenues per full-time primary care physician per year. All data were standardized against a single physician work-year being defined as 1 FTE MD, such that whether or not a physician works for 40 hours or 60 hours on average, their defined job role as a full-time clinician constitutes 1.0 FTE. Primary care practices were defined as either hospital- or non-hospital-based ambulatory general internal medicine or family practices.

The third stage of the model estimated practice expenses. The model calculates practice-level expenses in separate modules reflecting both personnel and overhead expenditures. Staffing ratios per full time physician and detailed compensation data were available from the IBM Kenexa Compensation Analysis<sup>7</sup>, summarized in Supplemental Appendix Table 2 and further detailed in a prior publication.<sup>8</sup> Additional overhead expenditures were taken from the Medical Group Management Association (MGMA)

DataDive database, and include staff benefits, building and occupancy, information technology, drug and medical supply, equipment and administrative supplies, liability insurance and fees, laboratory and imaging fees, and other ancillary service costs, detailed in **Supplemental Appendix Table 2**. Because the DataDive is not known to be nationally representative, we used a distributional decomposition method validated previously to weight DataDive entries to match the overall AHRQ distributions of utilization, charges, and revenues. All costs and revenues were updated to 2015 U.S. dollars using the Consumer Price Index 10. Validation plots are provided in **Supplemental Appendix Figure 2**.

#### 2 Medical home modeling strategy

We estimated the changes in encounters, empanelment, revenue and costs from incorporating more support staff, modifying visit templates, or extending evening/weekend business hours under each newly-piloted medical home funding approach by sequential repeated sampling from the input data reflecting how variations in provider, support staff, business hours and visit rates correlate to encounters and empanelment. Specifically, for support staff, data on the number of new encounters and number of newly-empaneled patients for each additional FTE of support staff by job title were estimated from national data collected by MGMA<sup>6</sup> (Supplemental Appendix Figure 1). By performing multivariate sampling across the staffing ratios of practices to identify the synergies between support staff FTEs, we captured how support staff contribute to the ability of providers to undertake encounters or empanelment, as well as contributing to operating costs and overhead (Supplemental Appendix Figure 1). Visit template alterations included extending visit length by 5 minutes, which lowers overall visit volume per day to accommodate the reported business hours by practice in the input data; we optimistically increased billing codes to the next higher level from baseline to account for the longer visit length. For telephone and electronic visits, we converted 10% of routine follow-up visits to electronic or telephone visits, reimbursed per state-and insurance-specific rates for CPT code 99444 for 10-minute electronic visits, or 99441 for 10-minute telephone visits. 11-13 We incorporated an additional 5 minutes documentation

time and additional infrastructure costs listed in main text Table 1, $^{11-13}$  and permitted the remainder of forfeited visits to be used for new or existing patient visits with the ratio of new patients to total for these new appointment slots varied from a baseline of 50% to a range of 25% to 75% in probabilistic sensitivity analysis. For evening and weekend business hours, data on the number of encounters per extended business hour were estimated from the Medical Expenditure Panel Survey; a log-linear model of annual visits per extended hour was used with intercept 1706, and slope 2461, multiplied by the log of new hours multiplied by 0.52, achieving  $R^2$ =93% across N=121,999 persons sampled. Costs included staffing per hour from an MD or mid-level provider at overtime salary rates, plus hourly overhead including building occupancy and utility costs as itemized in **Supplemental Appendix Table 2**.

To meet minimum PCMH funding requirements, support staffing costs included 0.23 FTE for a care coordinator (0.21-0.25), 0.31 FTE for an RN (0.28-0.34), 0.53 FTE for an LPN (0.50-0.56), and 1.11 FTE for an MA per FTE physician (1.09-1.13), according to a prior survey of *N*=502 transformed practices across the nation. In the primary data sources used to populate the model, primary care practices in the pre-PCMH-transformation period included 0 FTEs for a care coordinator (95% CI: 0-0), 0.43 FTEs for RNs (95% CI: 0.02-1.48), 0.76 FTEs for LPNs (95% CI: 0.14-1.85), and 1.23 FTEs for MAs (95% CI: 0.21-3.16) per FTE physician; and reported no electronic visits, telephone visits, or extended business hours.

#### 3 Model validation

We externally validated the model by comparing model estimates of clinic utilization to observed utilization from the National Ambulatory Medical Care Survey (N=31,229 patients) by age, sex, race/ethnicity, and insurance type. <sup>15</sup> We also validated the model's estimates of cost and revenue per full-time equivalent (FTE) physician against cost and revenue data reported in a survey of N=2,518 practices distributed across the country. <sup>16</sup> We finally compared model estimates of total operating cost per FTE physician and medical cost per patient visit to estimates from a national survey of patient-centered medical homes (N=679 practices). <sup>17</sup> As illustrated in **Supplemental Appendix** 

**Figure 2**, model estimates had less than 5% absolute error from the empirical data in all validation exercises.

#### 4 Optimization and implementation

For optimization, we utilized a previously-published generalized pattern search algorithm <sup>18</sup> to run the model across all possible combinations of workforce and time use changes to find the combination of providers, support staff, business hours and group visits to find the combinations that would maximize net revenue per FTE physician under each financing approach. We chose this algorithm over alternatives that are more susceptible to finding local but not global optima, <sup>19</sup> although this choice increased the computational run time for the model iterations.

The model was run 10,000 times in each simulation scenario to generate confidence intervals. Total model runtime including optimization and sensitivity analyses required approximately 96 hours of raw computing time on the Stanford Sherlock condominium server system, using 120 general compute nodes with dual socket Intel Xeon CPUs (E5-2650, version 2) running at 2.60GHz (8 core/socket) utilizing 64 GB 1866 MHz DDR3 RAM and 100 GB local storage, as well as 2 "big data" nodes with quad socket Intel Xeon CPUs (E5-4640) running at 2.40GHz (8 core/socket) utilizing 1.5 TB RAM and 13 TB local storage.

**Supplemental Appendix Table 1:** Summary distributions across demographic variables. For ease of visualization, the age and income categories are reported in aggregate groups here, while disaggregated estimates are available from the Census Bureau. Insurance coverage estimates are for the year 2013, after which estimates across years are provided by government models published previously, incorporating anticipated effects of the Affordable Care Act. Legend: Unins = uninsured.

Other insurance premiums	\$327 (107-1217)
Outside professional fees	\$1260 (238-4328)
Prof liability insurance	\$2032 (807-4543)
Promotion and marketing	\$361 (164-767)
Radiology and imaging	\$913 (183-2411)

Supplemental Appendix Table 3: Increased pay-for-performance success rate. Model-based estimates of change in net revenue per full-time physician for primary care clinics delivering patient-centered medical home (PCMH) services, as compared to the net revenue in the "status quo" clinic prior to PCMH transformation, when pay-for-performance success rate is increased from 10% (baseline) to 100%. Revenues include four funding scenarios—standard fee-for-service (SFFS), increased fee-for-service (IFFS), per member per month (PMPM), and per member per month with pay-for-performance bonus (PMPM+P4P). 95% confidence intervals are listed in parentheses from probabilistic sensitivity analyses in which the model was re-run 10,000 times while sampling from the probability distributions of all input parameters to generate confidence intervals around model results. Compare to main text **Table 2**.

Supplemental Appendix Table 10: High PCMH efficiency. Model-based estimates of change in net revenue per full-time physician for primary care clinics delivering patient-centered medical home (PCMH) services, as compared to the net revenue in the "status quo" clinic prior to PCMH transformation, when infrastructure costs of maintaining PCMH services are changed from \$2.96 per patient per month in the baseline assessment, to -\$5, reflecting high efficiency. Revenues include four funding scenarios—standard fee-for-service (SFFS), increased fee-for-service (IFFS), per member per month (PMPM), and per member per month with pay-for-performance bonus (PMPM+P4P). 95% confidence intervals are listed in parentheses from probabilistic sensitivity analyses in which the model was re-run 10,000 times while sampling from the probability distributions of all input parameters to generate confidence intervals around model results. Compare to main text **Table 2**.

**Supplemental Appendix Table 13:** Disaggregation of main text Table 2 to illustrate sources of mean revenues and costs before and after PCMH transformation under each financing strategy.

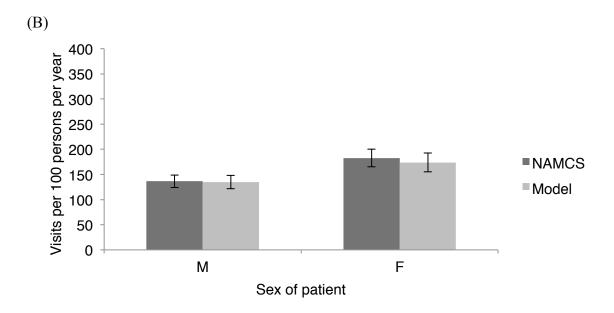

Payment model	SFFS	IFFS	PMPM	PMPM+P4P	
Visits per physician FTE	4,586	5,369	5,369	5,369	
Empaneled patients per physician FTE	2,349	3,827	3,827	3,827	
Gross revenue per physician FTE	\$487,390	\$543,079	\$700,378	\$709,886	
Costs per physician FTE					
Physician staffing and benefits	\$239,992	\$239,992	\$239,992	\$239,992	
Other staffing and benefits	\$133,788	\$127,664	\$127,664	\$127,664	
Non-staff costs	\$69,790	\$185,066	\$185,066	\$185,066	
Total costs	\$443,569	\$552,722	\$552,722	\$552,722	
Net revenue	\$43,821	-\$9,643	\$147,656	\$157,164	
Change in net revenue from SFFS	-\$53,464	\$103,835	\$113,343		

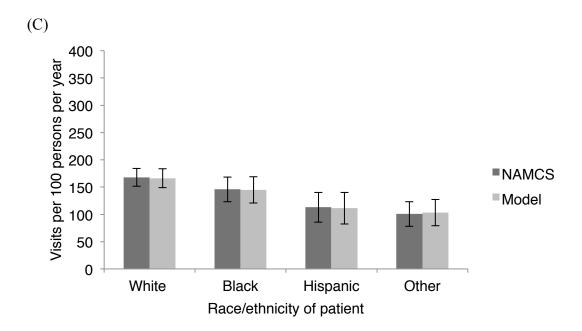

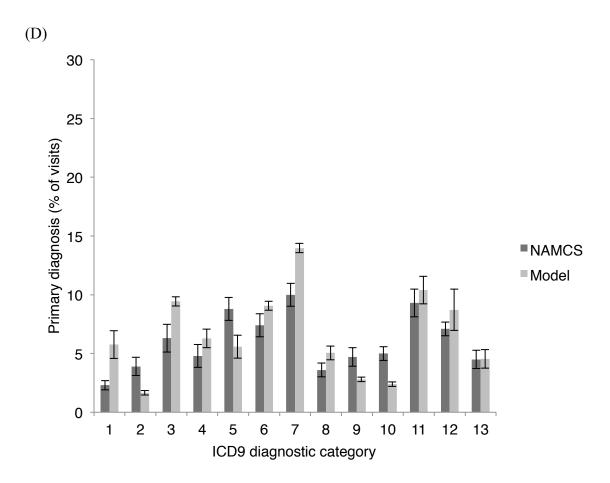

**Supplemental Appendix Figure 2:** Comparison of modeled utilization estimates to dat from the National Ambulatory Medical Care Survey (NAMCS, *N*=31,229 patients) specific to each (A) age, (B) sex, (C) race/ethnicity, (D) ICD-I diagnostic category and (E) insurance type (using historical insurance data without ACA correction) <sup>15</sup>; comparison of modeled (F) cost and (G) revenue estimates to data per physician FTE from a revenue and cost survey of 2,518 practices distributed across the country. <sup>16</sup>
